2.2.3	In the class <code>Blockchain</code> , implement the method <code>add_block</code> .	7
2.2.4	For each blockchain in the directory <code>blockchain_wallets</code> , compute the value of the wallet of each user.	7
2.2.5	In the class <code>Blockchain</code> , implement the method <code>check_legal_transactions</code>	8
2.2.6	For each blockchain in the directory <code>blockchain_incorrect</code> , check if it is correct.	9

# 1 Blockchain

## 1.1 Header Operations

### 1.1.1 Where is the address to the previous block stored?

The address to the previous block is stored in **previous hash** of the header.

### 1.1.2 implement `__init__`, `to_dict` and `to_json` in `block_header.py`

```
1 def __init__(self, index, previous_hash, timestamp, nonce):
2     # Store internally
3     self.index = index
4     self.previous_hash = previous_hash
5     self.timestamp = timestamp
6     self.nonce = nonce
7
8 def to_dict(self):
9     # Transform object into a dictionary for future transformation in JSON
10    # The name of the fields are the name of the variables
11    return self.__dict__
12
13 def to_json(self):
14    # Transforms into a json string
15    # use the option sort_key=True to make the representation unique
16    return json.dumps(self.to_dict(), sort_keys=True)
```

It is important to sort the keys because if the the order is different, the hash result will also be different. The order will ensure a universal encoding

### 1.1.3 Which of the header's fields is unnecessary and redundant?

The index is unnecessary and redundant, because in the chain, every block is already linked by a order with the known previous hash, there is no use in maintaining an index.

### 1.1.4 implement the method `read_header` which returns a header from a dictionary

```
1 def read_header(header):
2     # Implement these functions to help you
3     # Takes a dictionary as an input
4     return BlockHeader(**header)
```

### 1.1.5 Compare our header with the header of the Bitcoin. Which fields are missing? Describe briefly what they are used for.

The missing fields are:

**Version:** The version of the block.

**Merkle Root:** All of the transactions in this block, hashed together. Basically provides a singleline summary of all the transactions in this block.

**Bits:** A shortened version of the Target.

## 1.2 Transaction Operations

### 1.2.1 implement `__init__` and `to_dict` in the class `Transaction`

```
1 class Transaction(object):
2
3     def __init__(self, index, sender, receiver, amount):
4         # Store internally
5         self.index = index
6         self.sender = sender
7         self.receiver = receiver
8         self.amount = amount
9
10    def to_dict(self):
11        # Transform object into a dictionary for future transformation in JSON
12        # The names of the fields are the name of the variables
13        return self.__dict__
```

### 1.2.2 Which field is missing to make the transaction secured?

The signature of sender. Without the signature, the attacker can forge the sender's name to modify the transaction.

### 1.2.3 How is a person generally identified on a blockchain? How does a person prove ownership?

Through a public key, the ownership can be proven by the private key.

### 1.2.4 In the file block\_reader, implement the method read\_transaction which creates a Transaction from a dictionary.

```
1 def read_transaction(transaction):
2     # Same above for transformation
3     return Transaction(**transaction)
```

## 1.3 Block Operations

### 1.3.1 In the file merkle\_tree complete the function create\_merkle\_tree to implement the Merkle algorithm to store the transactions in the Merkle tree structure

Firstly, it is needed to define the classes for node and leaf:

```
1 class MerkleTreeNode(object):
2
3     def __init__(self):
4         self.parent = None
5         self.child_left = None
6         self.child_right = None
7         self.hash = None
8
9 class MerkleTreeLeaf(object):
10
11     def __init__(self, transaction):
12         self.parent = None
13         self.transaction = transaction
14         self.hash = compute_hash(transaction)
```

Then, in order to simplify and generalize the code, I modified the MerkleTree class in order to make it generate the nodes by itself (with the generate\_nodes method) from the leaves:

```
1 class MerkleTree(object):
2
3     def __init__(self):
4         self.root = None
5         self.nodes = [] # Stores all other nodes except the leaf nodes
6         self.leaves = [] # List of leaves of the tree. Leaves contain the transactions
7
8     def add_node(self, node):
9         # Add new node
10        self.nodes.append(node)
11
12    def add_leaf(self, leaf):
13        # Add new leaf node
14        self.leaves.append(leaf)
15
16    def generate_nodes(self, list = None):
17        temp = []
18        if list is None:
19            list = self.leaves
20        # create the nodes of this layer
21        if len(list) > 2:
22            for index in range(0, len(list), 2):
23                node = MerkleTreeNode()
24                node.child_left = list[index].hash
25                node.child_right = list[index+1].hash
26                node.hash = list[index].parent
27                temp.append(node)
28        # make binary
29        if len(temp) % 2 != 0:
30            temp.append(temp[-1])
31        # calculate the parents
32        for index in range(0, len(temp), 2):
33            temp[index].parent = compute_hash(temp[index].hash+temp[index+1].hash)
```

```

34         temp[index + 1].parent = compute_hash(temp[index].hash + temp[index + 1].hash)
35     for node in temp:
36         self.nodes.append(node)
37     self.generate_nodes(temp)
38     # for the root node
39     elif len(list)==2 :
40         node = MerkleTreeNode()
41         node.hash = list[0].parent
42         node.child_left = list[0].hash
43         node.child_right = list[1].hash
44         self.root = node
45         self.nodes.append(node)

```

Finally, for the function `create_merkle_tree`:

```

1 def create_merkle_tree(transactions):
2     # Using the Merkle algorithm build the tree from a list of transactions in the block
3     # transactions is list of Transaction
4     merkle_tree = MerkleTree()
5     for transaction in transactions:
6         merkle_tree.add_leaf(MerkleTreeLeaf(transaction))
7     # make sure that the tree can be binary
8     if len(merkle_tree.leaves) % 2 != 0:
9         merkle_tree.leaves.append(merkle_tree.leaves[-1])
10    # compute the parents of the leaves
11    for index in range(0, len(merkle_tree.leaves), 2):
12        merkle_tree.leaves[index].parent = compute_hash(merkle_tree.leaves[index].hash + merkle_tree.
13        leaves[index+1].hash)
14        merkle_tree.leaves[index+1].parent = compute_hash(merkle_tree.leaves[index].hash + merkle_tree.
15        leaves[index + 1].hash)
16    merkle_tree.generate_nodes()
17    return merkle_tree
18
19 def compute_hash(data):
20     to_hash = json.dumps(data, sort_keys=True).encode('utf-8')
21     return hashlib.sha256(to_hash).hexdigest()

```

### 1.3.2 What is the advantage of using the Merkle tree?

The Merkle Tree provide a way to prove both the integrity and validity of data. And the prove doesn't require a lot of memory. Moreover, the amount of information needed to be transmitted for a validation is also relatively low.

### 1.3.3 In the file `block.py`, implement the function `__init__`, `to_dict` and `to_json`

```

1 def __init__(self, header, transactions):
2     # Store everything internally
3     # header is a BlockHeader and transactions is a list of Transaction
4     # call create_merkle_tree function to store transactions in Merkle tree
5     self.N_STARTING_ZEROS = 4
6     self.header = header
7     self.transactions = transactions
8     pass
9
10 def to_dict(self):
11     # Turns the object into a dictionary
12     # There are two fields: header and transactions
13     # The values are obtained by using the to_dict methods
14     return self.__dict__
15
16 def to_json(self):
17     # Transforms into a json string
18     # use the option sort_key=True to make the representation unique
19     return json.dumps(self.to_dict(), sort_keys=True)

```

### 1.3.4 In the file `block_reader`, implement the method `read_block` and the method `read_block_json`

```

1 def read_block(block):
2     # Reads a block from a dictionary
3     return Block(read_header(block["header"]), block["transactions"])
4
5
6 def read_block_json(block_json):

```

```

7 # Reads a block in json format
8 return json.loads(block_json)

```

### 1.3.5 For each block in the directory blocks\_to\_prove compute its Merkle root.

The Merkle roots are calculated with the following code:

```

1 import os
2 from block_reader import *
3
4 dir = 'blocks_to_prove'
5 for file in os.listdir(dir):
6     with open(dir + '/' + file) as jsonp:
7         print("For block: " + file.title())
8         block = read_block(json.load(jsonp))
9         print("Merkle root: " + block.transactions.root.hash)

```

And the output:

```

1 For block: Block0.Json
2 Merkle root: e6fce6128396968905dfcbc4f746c6ec717797d7fb7c0e4635087c199312d6ff
3 For block: Block1.Json
4 Merkle root: dfb8e32a7387bab859cdabc4fabd6901cdd80a137c41d957abc0ffdda9570cca
5 For block: Block2.Json
6 Merkle root: 4524ff1a88bc683d2d3fb372f612a87eb67f4cef7e6cfe2e3a0fef9a0977d9d5
7 For block: Block3.Json
8 Merkle root: 3a59743e61fc35550ce833121abb32456a1b537686fd18c9f99fc8694d74e586
9 For block: Block4.Json
10 Merkle root: 1c376ce9154bf2789b063aa41b0faa5eccbb73e48f9b40d331eedc4c39d5ac56
11 For block: Block5.Json
12 Merkle root: e89ef529be1e17779551a34023fe55c3cc2d1daa7703a84294b80b4c23725b41
13 For block: Block6.Json
14 Merkle root: 8b639fbf820b8c1bc018455e94230e6c619b6b8f10f4240461e93946628ecc62
15 For block: Block7.Json
16 Merkle root: f347ffa02d0dca22b3d46aa61592d119bb1bac81c594b75750b3fa4ec930944b
17 For block: Block8.Json
18 Merkle root: 360951cbbda687be7970b610ab423081c4e2294b0860af1cf6055c398039ecb5
19 For block: Block9.Json
20 Merkle root: 3df239fa1e842f413e168aaade6bc90fc28c2df5cb37f75ff5d48578629ec76b

```

## 2 Block Mining

### 2.1 Proof-of-Work

#### 2.1.1 Why $H(x) = \frac{1}{2\pi}e^{-\frac{x^2}{2}}$ is a bad choice for pricing function?

We can plot this function:

From the plot, it can be easily observed that being a symmetric function, it is easy to find  $x \neq x'$  such that  $H(x) = H(x')$ , it is not collision resistant. Moreover, it is easy to find the inverse function  $x = \pm 2^{\frac{1}{2}}(-\ln(2\pi y))^{\frac{1}{2}}$ , so it is really easy to crack as we only need to try twice to get the  $x$  from a  $y$ .

#### 2.1.2 In the class BlockHeader, write the function set\_nonce. Why is nonce the only parameter we want to be able to modify?

```

1 def set_nonce(self, new_nonce):
2     # Set the nonce value
3     self.nonce = new_nonce

```

Because in order to compute a new hash, we need to change the input. The **nonce** can take any value. Other options like the transactions require the merkle root be recomputed, and the range of the timestamp is limited a range of acceptable times. So the nonce is the best option to ensure the proof-of-work mechanism without affecting the normal functions of the blockchain.

### 2.1.3 In the class BlockHeader, write the function get\_hash.

```

1 def get_hash(self):
2     # Use hashlib to hash the block using sha256
3     # Use hexdigest to get a string result
4     return hashlib.sha256(self.to_json().encode('utf-8')).hexdigest()

```

### 2.1.4 What is the advantage of hashing only the header and not the entire block?

Actually, as the header contains the *Merkle root* which is a hashing result of all the transactions, a hashing over the header is already a hashing over the entire block, but indirectly. Thus, with the same result, hashing only the header will save a lot of time and memory.

### 2.1.5 The huge security problem of the structure of our header

In the current structure, There is no Merkle root in the header, so there is the possibility of **Double-Spend Attack**, as the transactions cannot be confirmed by the hashing result of others.

### 2.1.6 In the class Block, implement the method is\_proof\_ready and make\_proof\_ready

```

1 def is_proof_ready(self):
2     # Check whether the block is proven
3     # For that, make sure the hash begins by N_STARTING_ZEROS
4     block_hash = self.header.get_hash()
5     return block_hash.startswith('0'*self.N_STARTING_ZEROS,0)
6
7 def make_proof_ready(self):
8     # Transforms the block into a proven block
9     nonce = 0
10    while not self.is_proof_ready():
11        nonce += 1
12        self.header.set_nonce(nonce)

```

### 2.1.7 For all blocks in the directory blocks\_to\_prove, prove it and give the nonce and the value of the hash function.

```

1 dir = 'blocks_to_prove'
2 print("block : nonce, hash")
3 for file in os.listdir(dir) :
4     with open(dir+"/"+file) as f:
5         block_dict=json.load(f)
6         block=read_block(block_dict)
7         block.make_proof_ready()
8         print(file[:-5]+" : "+str(block.header.nonce)+" , "+block.header.get_hash())

```

The output:

```

1 block : nonce, hash
2 block0 : 1438 , 0000aa66b0d1e8c3c7268f69d1ce2e39607c6ef33957a483c513b0372de1d2fe
3 block1 : 17773 , 000078ebc04a8c827de21e71eaddb5ce59d647999a3638433403cf7241bed27
4 block2 : 74441 , 0000234700122aca31d18901bb723fdc4cf7f71dd47ec55f11f71e3693dddb52
5 block3 : 135140 , 0000180be1b98053bd2e0433c78d38d630afc5e45f91ede9dac86f4e704f1a80
6 block4 : 25067 , 0000bef8730d5c78679f854d0771b3d7fd9fce926df2e9d52391d7331ab981b9
7 block5 : 37716 , 000085656a163e42a67346007bab61ad890452f00832654c4020181d8afd140e
8 block6 : 22454 , 0000e41bbe5a1cb64a40e2e9d59da8994abae6df9345ec115d77781484a58bd8
9 block7 : 27395 , 0000a76aa2b0308782cedcf01a1958401bf2a219147588248dd8a2d0d3d74292
10 block8 : 188002 , 00006e24a6ddccbb6423d7ddaae7161f79cf863d45337f2b4bc9c6a650fe83eb
11 block9 : 59304 , 00009cc0b80cee2c556d93226e3802bb75c5e9c3ca7127d64165e833c605e8aa

```

### 2.1.8 Take one block from the directory blocks\_to\_prove and observe what happens when you increase the number of requested starting zeros in the proof.

For the block block0.json, the running time needed to prove also increased as I increased the number of requested starting zeros.

From 7 leading zeros, the computation of the proof takes more than one minute.

According to the block published at 2020-01-17 19:01, there are 18 leading zeros:

(00000000000000000010effc63faf969a85aa1ed60d70f48d2ade85f8f4c49ec).

## 2.2 Verification

### 2.2.1 In the file block\_reader, implement the method read\_chain

```
1 def read_chain(chain):
2     # read the chain from a json str
3     # Returns a list of Block
4     # This method does not do any checking
5     return [read_block(item) for item in json.loads(chain)]
```

### 2.2.2 In the class Blockchain, implement the method update\_wallet

```
1 def update_wallet(self, block):
2     # Update the values in the wallet
3     # We assume the block is correct
4     for temp in block.transactions.leaves:
5         transaction = temp.transaction
6         self.wallets[transaction.sender] = self.wallets.get(transaction.sender, 0) - transaction.
amount
7         self.wallets[transaction.receiver] = self.wallets.get(transaction.receiver, 0) + transaction.
amount
```

### 2.2.3 In the class Blockchain, implement the method add\_block.

```
1 def add_block(self, block):
2     # Add a block to the chain
3     # It needs to check if a block is correct
4     # Returns True if the block was added, False otherwise
5     if block.is_proof_ready() and self.check_legal_transactions(block):
6         self.chain.append(block)
7         self.update_wallet(block)
8         return True
9     else:
10        return False
```

### 2.2.4 For each blockchain in the directory blockchain.wallets, compute the value of the wallet of each user.

We test as below:

```
1 dir = 'blockchain_wallets'
2 for file in os.listdir(dir):
3     with open(dir + '/' + file, "r") as f:
4         block_chain = Blockchain()
5         for block in read_chain(f.read()):
6             block_chain.add_block(block)
7         print("For " + file + " :")
8         for (k, v) in block_chain.wallets.items():
9             print(k + ": " + str(v))
```

The result:

```
1 For chain0.json :
2 admin: 999999999999940
3 alice: 23.066764710084918
4 bob: 6.989223624959041
5 fabian: 11.523123986955143
6 nicoleta: 5.216826891046529
7 jonathan: 30.33862527879706
8 julien: -17.13456449184271
9 For chain1.json :
10 admin: 999999999999940
```

## 2.2.5 In the class Blockchain, implement the method check\_legal\_transactions

```

1 def check_legal_transactions(self, block):

```

```

2     # Check if the transactions of a block are legal given the current state
3     # of the chain and the wallet
4     # Returns a boolean
5     wallets_copy = self.wallets.copy()
6     for temp in block.transactions.leaves:
7         transaction = temp.transaction
8         balance = wallets_copy[transaction.sender]
9         if balance < transaction.amount:
10            return False
11        else:
12            wallets_copy[transaction.sender] = wallets_copy.get(transaction.sender, 0) - transaction.
13            amount
14            wallets_copy[transaction.receiver] = wallets_copy.get(transaction.receiver, 0) +
15            transaction.amount
16        return True

```

## 2.2.6 For each blockchain in the directory blockchain\_incorrect, check if it is correct.

It is checked as below:

```

1 dir = 'blockchain_incorrect'
2 for file in os.listdir(dir):
3     with open(dir + '/' + file, "r") as f:
4         block_chain = Blockchain()
5         correct = True
6         for block in read_chain(f.read()):
7             if not block_chain.add_block(block):
8                 print(file[:-5] + ' incorrect, first error in block ' + str(block.header.index))
9                 correct = False
10                break
11        if correct:
12            print(file[:-5] + ' is correct')

```

The result:

```

1 chain0 incorrect, first error in block 4
2 chain1 incorrect, first error in block 7
3 chain2 incorrect, first error in block 3
4 chain3 incorrect, first error in block 4
5 chain4 incorrect, first error in block 2
6 chain5 incorrect, first error in block 3
7 chain6 incorrect, first error in block 2
8 chain7 incorrect, first error in block 3
9 chain8 incorrect, first error in block 4
10 chain9 incorrect, first error in block 2

```
